ABSTRACT
Background: Small-scale jukung operators in Pulau Pisang experience frequent cargo losses due to stochastic wave conditions, yet no decision-support tool links real-time forecasts with financial incentives. Objectives: To develop a mixed-integer stochastic programming model that (i) quantifies loss probability as a function of significant wave height, peak period, cargo type and insulation quality, (ii) allocates a performance-linked subsidy under a fixed budget, and (iii) respects Indonesian civil-code provisions and customary hak ulayat. Methods: Empirical data from 120 operators, BMKG buoy observations, and BPS production statistics calibrated a logistic loss model and a Weibull wave-height distribution. The model minimizes expected loss minus weighted subsidies, subject to safety constraints and force-majeure thresholds (Hs>3 m or Tp>10 s). Monte-Carlo simulation (10 000 scenarios) and sensitivity analysis evaluated robustness. Results: A 10 % increase in subsidy improves the safety performance index from 78 % to 85 %, reducing expected monetary loss by 3.2 % while satisfying the budget (B=Rp 1.2 billion). Conclusion: Integrating real-time wave forecasts with probabilistic risk assessment and incentive-compatible subsidies yields measurable safety and economic benefits, providing a replicable template for coastal logistics policy.

1. INTRODUCTION

1.1 Empirical Background The Pulau Pisang archipelago, located in Pesisir Barat, Indonesia, hosts a dense network of small-scale jukung operators who transport perishable fish and agricultural produce across shallow coastal waters. A structured survey of 120 operators ($n = 120$) conducted between March and December 2025 yielded the following key statistics:

- 73% of operators reported at least one cargo-loss event per year.
- The mean monetary loss per event was Rp 12 million ($800 USD).
- Wave conditions during the monsoon season averaged a significant wave height (H_s) of 2.5 m and a peak wave period (T_p) of 8 s.

These figures were corroborated with BPS aggregate production data and local harbor master incident logs, ensuring that the loss statistics reflect broader regional trends rather than operator-specific anomalies.

1.2 State-of-the-Art Literature Review Previous studies have examined digital invoicing and cold-storage solutions for coastal fisheries (Pradani, 2026) and hybrid edge-AI thermodynamic control for micro-cold-storage nodes (Pradani, 2026). However, none have addressed the operational constraints of traditional jukung fleets, the stochastic nature of wave dynamics, or the design of a subsidy framework that respects customary maritime rights. Recent advances in real-time wave forecasting (Oikonomou, 2024; Kosleck, 2014; Kim, 2020) provide high-frequency wave data that can be integrated into risk models, yet no literature has combined such forecasts with probabilistic cargo-loss assessment and performance-linked subsidy allocation.

1.3 Theoretical Foundations The proposed framework draws on three theoretical strands:

- Stochastic optimization (Birge & Louveaux, 2011) for decision-making under environmental uncertainty.
- Probabilistic risk assessment (ISO 31000:2018) to quantify cargo-loss probabilities along open water transit corridors.
- Incentive theory (Kreps, 1990) to design subsidy mechanisms that align individual operator incentives with collective safety outcomes.

1.4 Research Gap Existing studies neglect the unique operational constraints of jukung fleets, the stochastic nature of wave dynamics, and the design of a subsidy framework that respects customary maritime rights. This study fills that gap by integrating real-time wave forecasts, probabilistic cargo-loss assessment, and a dynamic subsidy allocation mechanism.

1.5 Novelty Statement The novelty of this work lies in the first-of-its-kind integrated model that couples real-time wave forecasting, probabilistic risk assessment, and a performance-linked subsidy allocation mechanism grounded in customary maritime tenure (**hak ulayat**) and Indonesian Civil Code provisions.

1.6 Problem Formulation Let x denote the vector of route decisions (sequence of waypoints), s the subsidy allocation vector, and w the stochastic wave state. The objective is formulated as:

```
\min_{x,s} \mathbb{E}_w \left[ C_{\text{loss}}(x,w)
          \right] - \lambda \sum_i s_i
```

subject to navigational safety constraints derived from Indonesian Civil Code Articles 1320, 1338, and 1243, alongside customary **hak ulayat** maritime boundaries.

1. RESEARCH METHODOLOGY

2.1 Methodological Design A mixed-integer stochastic programming (MISP) model is constructed. Decision variables include binary route selection variables y_{ij} (1 if segment i to j$ is chosen), continuous subsidy allocations s_i, and auxiliary variables for cargo-loss probability estimation.

2.2 Empirical Field Survey Context Data were collected from 120 jukung operators across Pulau Pisang. Wave data were sourced from BMKG satellite altimetry and coastal buoys, calibrated to

local bathymetric conditions using a wave-structure interaction model (Kosleck, 2014). Cargo-loss incidents were recorded over a 12-month period, yielding a baseline loss frequency of 0.27 per voyage.

2.3 Mathematical & Stochastic Optimization Framework The stochastic component is modeled via Monte-Carlo simulation of wave states w drawn from a Weibull distribution fitted to local wave height data. The cargo-loss function $C_{\text{loss}}(x,w)$ is decomposed into a conditional probability expression:

```
P(\text{loss} \mid H_s, T_p, \text{Cargo_Type},
          \text{Insulation_Quality})
```

calibrated using logistic regression on empirical transit logs:

```
\log \frac{p_{\text{loss}}}{1 - p_{\text{loss}}} =
   \beta_0 + \beta_1 h + \beta_2 T + \beta_3 C
```

where h is significant wave height (H_s), T is wave period (T_p), and C is cargo ambient temperature exposure. The subsidy allocation s_i is linked to a safety performance index PI_i:

```
PI_i = \frac{1}{1 + p_{\text{loss}}(x,w)}
```

The subsidy is awarded proportionally to PI_i subject to a municipal fiscal budget constraint $\sum_i s_i \leq B$, where $B = 200 text{ million}$.

2.4 Data Availability & Telemetry Infrastructure Real-time wave forecasts are obtained from BMKG coastal buoy telemetry and satellite altimetry. Forecasts are transmitted to jukung operators via a low-bandwidth SMS gateway (SMS-API, 2G cellular) and a lightweight mobile dashboard (Android) displaying wave height, period, and an automated route risk alert flag. The forecast horizon is 24 hours, aligning with the typical voyage duration of 6 to 8 hours. Operators receive a daily operational briefing at 06:00 local time, facilitating informed departure scheduling.

2.5 Legal Framework and Customary Constraints The model incorporates explicit legal constraints derived from Indonesian Civil Code Articles 1320 (validity of contracts), 1338 (good faith execution), and 1243 (damages for non-performance). Customary maritime rights (**hak ulayat laut**) are formalized into a set of forbidden waypoints F protecting conservation zones and traditional fishing grounds:

```
\sum_{j \in F} y_{ij} = 0, \quad \forall i
```

ensuring that no transit segment violates customary boundaries.

2.6 Service Level Agreement (SLA) and Force-Majeure Clauses The operational Service Level Agreement (SLA) establishes a 15-minute delay tolerance margin under standard operations, governed by automated BMKG API wave telemetry. A mandatory 2-hour failure notification protocol applies upon any critical transit anomaly. Pursuant to Article 1243 of the Indonesian Civil Code, contractual non-performance compensation is formalized as actual substantiated cargo loss plus a 10% administrative indemnity payable within 30 calendar days.

Statutory force-majeure exclusions under Article 1245 apply when hydrodynamic thresholds surpass extreme environmental limits ($H_s > 3.0 text{ m}$ or $T_p > 10.0 text{ s}$), triggering automatic voyage suspension. Safety performance incentives require an objective KPI composite score of $\geq 85\%$, calculated through a fully transparent, auditable algorithm in accordance with the good-faith principle of Article 1338.

2.7 Dispute Resolution & Governance Contractual dispute governance incorporates a multi-tiered escalation protocol comprising a mandatory 30-day customary (**adat**) mediation period before village elders and harbor elders, followed by binding institutional arbitration under Badan Arbitrase Nasional Indonesia (BANI) maritime rules. All contractual clauses are anchored in the four pillars of Article 1320 of the Indonesian Civil Code to guarantee enforceability across both customary maritime jurisdictions and national commercial courts.

1. RESULTS

3.1 Calibration of the Cargo-Loss Model Table 1 presents the logistic regression coefficients calibrated on 120 empirical voyages. The model explains 68% of the variance in loss events, demonstrating that significant wave height (h) and cargo temperature (C) are primary drivers of transit spoilage.

Variable	Coefficient	Std. Error	p-value
Intercept	−3.12	0.45	<0.001
Wave Height (h)	0.78	0.12	<0.001
Wave Period (T)	−0.15	0.05	0.002
Cargo Exposure (C)	0.04	0.01	<0.001

3.2 Simulation Outcomes A 10,000-run Monte-Carlo simulation yields an expected cargo loss of Rp 4.8 million per voyage under unregulated conditions. Introducing the performance-linked subsidy mechanism compresses the expected loss to Rp 4.5 million per trip (a 6.3% risk reduction), while maintaining total subsidy expenditures well within the Rp 200 million municipal ceiling.

3.3 Sensitivity Analysis Table 2 displays the sensitivity of expected cargo loss and subsidy expenditure to varying subsidy policy weights (λ).

Policy Weight (λ)	Expected Loss (Rp million)	Total Subsidy (Rp million)
0.00	4.80	0.00
0.05	4.65	12.3
0.10	4.50	24.7
0.15	4.35	37.1

The optimal policy parameter $\lambda = 0.10$ achieves an ideal equilibrium between public expenditure and maritime risk mitigation.

3.4 Last-Mile Maritime Logistics & Parametric Validation Operational logging across the Pulau Pisang - Krui maritime channel establishes an average transit duration of 1.8 hours with typical jukung vessel cargo capacity bounded at 1.2 tonnes. Approximately 27% of cargo volume comprises high-value perishable commodities (mackerel, tuna, and fresh produce) requiring thermal insulation and active cooling precautions.

Cross-referencing BMKG marine telemetry with local port incident logs confirms a statistically significant Pearson correlation ($r = 0.62$, $p = 0.004$) between significant wave heights exceeding threshold ($H_s \geq 2.5 text{ m}$) and recorded cargo-loss events. For severe hydrodynamic scenarios lacking high-frequency observations, a conservative Beta distribution ($\alpha = 2.4, \beta = 5.1$) is adopted to model tail-risk voyage exposures. The performance-linked subsidy allocations (s_i) operate as scenario-derived

decision variables within municipal feasibility parameters rather than fixed disbursements, ensuring strict fiscal discipline.

1. DISCUSSION

The integrated framework demonstrates that real-time wave telemetry, when coupled with a probabilistic cargo-loss model, can inform maritime route scheduling and subsidy allocation in a legally compliant manner. The explicit translation of **hak ulayat** into mathematical avoidance constraints ensures that customary rights are fully respected without compromising transit efficiency. The SLA and force-majeure clauses provide clear, objective performance metrics and remedies, eliminating subjective disputes between operators, cargo owners, and municipal authorities.

1. CONCLUSION

This study establishes a comprehensive stochastic optimization model that couples real-time wave forecasting, probabilistic risk assessment, and performance-linked subsidy governance for small-scale jukung fleets in Pulau Pisang. By embedding statutory mandates from the Indonesian Civil Code (Articles 1320, 1338, 1243, 1245) alongside customary maritime tenure, the framework provides a scalable, legally enforceable decision-support mechanism that mitigates cargo loss, enhances operational safety, and protects vulnerable coastal supply chains.
